

Loan Prediction

Data Science Project

By Majid Sadeghinejad, Amir Shahang, Erfan Soleymani

Introduction

The dataset contains financial information about Indian individuals such as house and car ownership, annual income, Age, Marital status, occupation and living state. And we have a field, risk flag, that shows the person has defaulted on the loan or not.

Our goal is to find out which fields and properties can predict the Risk of default on a loan or even a check better and more effectively. And after that create a model to predict that takes a person's financial information and predict he/she might default on loan or not.

Phase one: Visualizing

After downloading the dataset from kaggle website we are going to visualize our data using Microsoft Power Bi to achieve a better understanding of data and its fields.

Using bar charts and cards we are going to show the effect of below factors on Risk flag our. Our measure for the risk flag is 0 (hasn't defaulted) and 1 (has defaulted) . We are gonna use the average risk flag for each category in each factor and show the result. In all Dashboards you can filter the charts by clicking on bars.

- **Dashboard 1: Occupation factors effect**
 - Duration of employment
 - Experience
 - Income
 - Profession
- **Dashboard 2: Personal factors effect**
 - Age
 - Marital status
- **Dashboard 3: Life factors effect**
 - Car ownership
 - House ownership
- **Dashboard 4: India states status**
 - General map
 - states
